

ECONOMY & INVESTMENT BRIEF · CONFIDENTIAL

Where the money comes from.

How tokens work, how ours works, how the business earns real revenue, and what makes it investable — explained from zero.

Prepared for	Version	Supersedes	Status
Incoming partner onboarding	2.0 · August 2026	Revenue Economy Blueprint v1	Pre-revenue · development stage

The one thing to understand first

Almost every misunderstanding about crypto businesses comes from mixing up two completely separate systems. Get this right and everything else in this document follows easily.

SYSTEM ONE

The game economy

Runs on \$MOVE, our in-game token.

- Players earn it by moving
- Players spend it inside the game
- Spending destroys most of it
- Almost no cash enters or leaves

The game's fuel — not our income.

SYSTEM TWO

The business

Runs on ordinary money, in ordinary ways.

- Sponsors pay to back zones
- A small fee on land trades
- An optional paid subscription
- Events, clubs, and analytics

This is our actual revenue.

Two separate systems. The token makes the game work. The business pays the bills.

WHY THE SEPARATION IS THE WHOLE STRATEGY

The move-to-earn apps that collapsed in 2022 had only System One. Their business was the token, so when the token fell, the company had no income and the product died with it. **MovenRun is built so that if \$MOVE were worth nothing at all, the business would still have customers paying real money.** That is the most important structural decision in this document, and it is the first thing a serious investor will look for.

How numbers are labelled

Figures come from two very different places, and every one is labelled so you never have to guess:

LABEL	WHAT IT MEANS
FROM OUR CODE	A real parameter written into our smart contracts. Anyone can verify it on the public blockchain.
ILLUSTRATIVE	A modelled figure showing how the maths behaves. Not a forecast. No paying customer has validated it.
PLANNED	A designed mechanism that is not live yet.

SAY THIS OUT LOUD IN ANY INVESTOR CONVERSATION

Every revenue figure in Part C is **illustrative**. We have no paying customers, no signed sponsors, and no validated pricing. Presenting a model as a projection is the fastest way to lose an investor's trust — and saying plainly *"this is our model, here are the assumptions, none of it is proven yet"* is the fastest way to earn it.

Contents

A	Tokens, from zero	1–5 · what a token is, where it comes from, why economies fail
B	The MovenRun token economy	6–15 · how \$MOVE is created, held, spent and destroyed
C	How the business makes money	16–23 · revenue lines, costs, and city-level economics
D	What attracts investment	24–30 · the investor lens, applied honestly

What a token actually is

Forget everything you have heard about crypto for two minutes. A token is a much simpler idea than the noise around it suggests.

Start with a shared notebook

Imagine a notebook in a village square. Anyone can write in it, everyone can read it, and once something is written it can never be erased — you can only add a new line. Thousands of people keep identical copies, so if one person forges their copy, every other copy disagrees and the forgery is rejected.

That notebook is a **blockchain**. It is not a currency or a company. It is just a way of keeping a record that nobody controls.

A token is a number in that notebook

If the notebook can record who owns what, it can record quantities too. A **token** is simply a balance written in it: *"address #4821 holds 350 units."* That is the whole idea. What makes tokens interesting is not the technology — it is the **rules** attached to them, which are also written into the notebook and cannot be quietly changed later.

The rules are the product

How many can ever exist, who can create new ones, what they can be used for, and what destroys them. These rules *are* the tokenomics.

Nobody can cheat them

The rules run as a program on the blockchain. Not even the company that wrote them can print extra tokens or change the cap afterwards.

That is why it is used at all

A company database can be edited overnight. A public ledger cannot. That credibility is the only reason to bother with any of this.

Two kinds of token, and the difference matters legally

KIND	WHAT IT IS	EVERYDAY ANALOGY
Fungible (our \$MOVE)	Every unit is identical and interchangeable. Balances, not objects.	Cash, or arcade tokens
Non-fungible (NFT) (our Zone Deeds)	Each one is distinct and individually identifiable.	A title deed to a specific house

NFTs became famous through cartoon profile pictures, which is an unhelpful association. The underlying idea is just *"this specific unique thing belongs to this specific person, recorded where nobody can revoke it."* Land registries and certificates are the natural use — and ours is literally a land registry.

THE SENTENCE TO REMEMBER

A token is a balance in a ledger nobody owns, governed by rules nobody can secretly change. Everything else in Part A is about who gets to create those balances, and why anyone would want one.

Where tokens come from

Somebody has to create the first token. *How* they are created is the single biggest fork in the road between a project that lasts and one that does not.

MODEL 1

Mined into existence

Bitcoin. Tokens are created as a reward for doing costly work that secures the network.

Fair, slow. Useless for a consumer app.

MODEL 2

Pre-made and sold

The team creates the entire supply on day one and sells a slice to investors and the public.

Fast money. Insiders hold everything.

MODEL 3

Emitted for activity

New tokens are printed continuously to reward users for doing something — steps, posts, trades.

This is what killed move-to-earn.

MODEL 4 — OURS

Earned, capped, and burned

Emitted only for **proven** activity, from a pool that shrinks each season, with most of it destroyed again.

Model 3 with brakes fitted.

Four ways new tokens come into existence. Only the fourth has a mechanism for taking them back out.

Model 3 in detail, because it is the one we had to fix

"Emitted for activity" sounds ideal: users do something useful, the protocol rewards them, everyone wins. It fails for a reason that is obvious in hindsight.

If the only way tokens enter is *printing*, and the only thing a user can do with them is *sell*, then supply rises forever while demand depends entirely on new buyers arriving. The moment new buyers slow down, the price falls; the moment the price falls, the reward is worth less; the moment the reward is worth less, users leave — which slows new buyers further. It is a spiral with no floor.

What MovenRun does differently — three changes

1. **Tokens are only created for *proven* movement.** There is no faucet, no airdrop, no "connect wallet and claim". A cryptographic proof that someone genuinely moved is required before a single token exists. See Section 14.
2. **The supply that can be created is capped and shrinking.** Every season issues from a fixed pool, and each pool is deliberately smaller than the last. See Section 10.
3. **Most tokens are destroyed by playing the game.** Claiming land, fortifying it, challenging a rival — all of it consumes tokens permanently. See Section 12. This is the piece the previous generation simply did not have.

THE DESIGN RULE WE FOLLOWED

Decide how tokens leave the system before deciding how they enter it. That order is unusual, and it is the reason our economy has a reason to exist beyond new buyers arriving.

How a token gets a price

This is the part people find most mysterious, and the part that matters least to our business. Both facts are worth understanding.

A token has no price until someone trades it

A token sitting in a ledger has no value, the way a concert ticket nobody wants has no value. A price only exists once there is a **market** — a place where someone will exchange the token for something else, usually a stable currency.

In crypto that place is usually an automated pool: the team (or anyone) deposits, say, 100,000 tokens alongside \$100,000 of stable currency. The pool then quotes a price from the ratio between the two sides, and it moves as people buy or sell. Buying takes tokens out and pushes the price up; selling puts tokens in and pushes it down.

A token price is only ever the balance between these two columns. Our design work is almost entirely about the left column.

Why our business does not depend on this

Here is the crucial commercial point. **MovenRun's revenue is not the token price.** When a café pays to sponsor a zone, that is a normal invoice in normal currency. When someone subscribes to premium tools, that is a normal subscription. Neither transaction cares what \$MOVE trades at.

The token price matters to us in exactly two ways: it affects how *rewarding* the game feels to crypto-native players, and a healthy economy makes land more desirable. Both are real, and neither is our income statement.

SAY THIS PRECISELY

\$MOVE does not trade anywhere today. There has been no sale, no listing, no liquidity pool, and no allocation to anyone. It exists only as a test-network contract with no value. **Never describe it as an investment, never quote or estimate a price, and never imply anyone will earn income from it.** That is both the honest position and the legally safe one.

Why crypto economies collapse

Four failure patterns account for nearly all of it. Every design decision in Part B is a direct answer to one of them, so it is worth knowing them by name.

1 The printing spiral

What happens: tokens are printed as rewards, users immediately sell them, supply grows faster than demand, price falls, rewards become worthless, users leave.

Our answer: a fixed season pool that shrinks each season, so total issuance is bounded and declining rather than proportional to how many people show up (§10). Plus sinks that destroy far more than a typical game ever collects back (§12).

2 Rewards with nowhere to go

What happens: the token has no genuine use inside the product, so the only rational action on receiving one is to sell it. Every reward becomes immediate sell pressure.

Our answer: you cannot claim land, fortify it, challenge a rival, run a club, or enter a season without spending \$MOVE. The most committed players are net *consumers* of the token, not net sellers (§12).

3 Free-farm-to-dump

What happens: anyone can sign up, farm rewards at zero cost, sell them, and repeat with a new account. The economy funds its own attackers.

Our answer: two reward states (§8). Free players earn **Locked MOVE**, which can be spent inside the app but can never be transferred or sold. Only active Zone Deed holders — people who have already spent to acquire and defend land — can earn sellable rewards, and even then only from a capped pool. Crucially, **upgrading does not unlock old rewards**: locked stays locked forever.

4 The company that was only a token

What happens: the project's entire income is token sales and token appreciation. When the market turns, there is no revenue, no runway, and no reason for the team to stay.

Our answer: the whole of Part C. Sponsors, land fees, subscriptions, and events are paid in ordinary money by people who want something other than a token.

The four brakes, at a glance

Shrinking pools
bounded issuance

Real sinks
spending destroys

Locked rewards
no free-farm dump

Real revenue
income without price

What "digital land" really means

The phrase sounds like science fiction. The mechanism is closer to a parking permit than to buying a field.

The map is divided into permanent cells

We lay a honeycomb over the entire planet using an open standard called **H3**, originally built by Uber. Every point on Earth belongs to exactly one hexagon with a permanent identifier. Our cells are about **0.74 km²** each [FROM OUR CODE](#) — roughly a small neighbourhood. Two people standing on the same corner are always in the same zone, anywhere in the world.

A Zone Deed is a record that a specific cell is yours

When someone claims a cell, an entry is written to the public ledger: *"hexagon #8828308281 belongs to address #4821."* That entry is the **Zone Deed**. It is not a picture of a place — for the game's purposes, the deed *is* the place. It carries who holds it now, the history of how it changed hands, how strongly it is defended, and what it has earned.

WHAT IT IS NOT — BE PRECISE ABOUT THIS

A Zone Deed is **a game asset, not real-world property**. It confers no rights over the physical land, no access, no planning permission, and no relationship with whoever actually owns the ground. Anyone who implies otherwise is misrepresenting the product.

Why scarcity is real here, and not manufactured

Most digital scarcity is arbitrary — a team simply declares that only 10,000 items will exist. Ours is bounded by geography and by effort:

There is only one of each place

The hexagon containing the main square of your city exists exactly once, for ever. No amount of demand creates a second one. That is genuine, non-arbitrary scarcity.

Land must be earned, not just bought

A cell only becomes claimable once **at least 5 distinct people** have genuinely moved through it over 90 days [FROM OUR CODE](#). One person cannot manufacture a valuable district alone.

Busy land costs more

The claim price scales with how active the cell is — **500 × √(weekly movers)** [FROM OUR CODE](#). A quiet suburb is cheap; a busy high street is expensive, automatically.

Holding it costs effort

Rivals can challenge your land, and a cell left untouched for 180 days can be flagged and eventually reclaimed [FROM OUR CODE](#). Land is a commitment, not a collectible.

WHY THIS MATTERS COMMERCIALY

Scarcity that comes from geography plus verified effort is far harder to copy than scarcity that comes from a press release. A competitor can clone our app in a quarter; they cannot clone the fact that the people in your neighbourhood already hold the ground around your street.

\$MOVE at a glance

The complete specification of our token on one page. Everything here marked "from our code" is written into contracts already deployed to Base's public test network and can be independently verified.

PROPERTY	VALUE
Name and symbol	MoveToken · \$MOVE FROM OUR CODE
Chain	Base — an Ethereum Layer 2 FROM OUR CODE
Maximum supply, ever	1,000,000,000 — a hard cap the contract cannot exceed FROM OUR CODE
How new tokens are created	Only against a cryptographic proof of verified movement FROM OUR CODE
Anti-farming cap	200 \$MOVE per address per day at launch, halving each epoch FROM OUR CODE
Reward states	Locked (non-transferable) and Liquid (transferable, capped) PLANNED
Land tax	2% of everything minted inside a cell goes to that cell's deed holder FROM OUR CODE
Loyalty bonus	Defensive strength rises with holding time, up to 1.75× FROM OUR CODE
Season length	90 days FROM OUR CODE
Gear boost ceiling	3× maximum, enforced in the contract FROM OUR CODE
Currently tradeable?	No. No sale, no listing, no liquidity, no allocation. Test network only.

Intended supply distribution

PLANNED — NONE OF THIS HAS BEEN EXECUTED

Team tokens carry a 12-month cliff and 36-month linear vesting — meaning the team cannot sell anything for a year, then only gradually.

WHY THE 60% MATTERS TO AN INVESTOR

The majority of the supply is reserved for the people who actually move — not for insiders. Combined with a 12-month team cliff, this is the distribution shape investors look for when judging whether a team intends to build or to exit. A project with 40% to insiders and no cliff signals the opposite.

How a user actually gets tokens

Follow one real morning walk from the first step to the balance appearing. This is the whole creation mechanism, end to end.

Nothing reaches the blockchain unless every check passes. The contracts trust the proof, never the phone.

The worked example

Priya walks **5 km**. In the current contract the rate is 10 \$MOVE per kilometre, so:

STEP	AMOUNT
5 km × 10 \$MOVE per km FROM OUR CODE	50 \$MOVE
She has a 1.5× gear item equipped PLANNED	× 1.5 → 75 \$MOVE
Daily cap check — well under the 200 limit FROM OUR CODE	no reduction
2% land tax to whoever owns the cell she crossed FROM OUR CODE	– 1.5 \$MOVE
Credited to Priya	73.5 \$MOVE

Because Priya is a free player who does not own land, her 73.5 arrives as **Locked MOVE** — real, spendable inside the game, but never sellable. The 1.5 that went as land tax goes to a Zone Deed holder as **Liquid** earnings. That single line is the entire two-state economy in miniature, and Section 8 explains why it matters so much.

AN HONEST NOTE ON THE RATE

The "10 \$MOVE per km" figure is what our deployed test contract does today. Our economic design has since moved to a better model — a fixed seasonal pool shared by all active players, rather than a fixed rate per kilometre. Section 10 explains why, and flags this as a change that must be made in the next contract version. **This is the kind of discrepancy worth volunteering to an investor rather than being caught on.**

One token, two states

This is the most important mechanism we have, and the clearest answer to "how is this not another move-to-earn?". Users feel one simple economy; underneath, the protocol keeps engagement and market liquidity apart.

STATE ONE

Locked MOVE

Earned by every free player.

- ✓ Spend it on captures, upgrades, fortifying, clubs, and events
- ✗ Cannot be transferred
- ✗ Cannot be sold or withdrawn
- ✗ Never converts, even later

Real progress. Zero sell pressure.

STATE TWO

Liquid MOVE

Earned only by active landowners.

- ✓ Everything Locked can do
- ✓ Transferable and sellable
- ! Capped by the season pool
- ! Requires holding and defending land — which costs tokens first

Real upside. Earned, capped, defended.

The same token, held in two different states. Which state you earn in depends on whether you have skin in the game.

The rule that makes it work

THE NO-RETROACTIVE-UNLOCK RULE

When a free player later becomes a landowner, **their existing Locked balance stays locked for ever**. Only rewards earned *after* they qualify can be Liquid. This single rule closes the loophole that would otherwise sink the whole design: farm for months on free accounts, upgrade once, and cash out everything at once.

Why this is fair rather than a paywall

It would be easy to read this as "free players get the worthless version". It is the opposite, for three reasons:

- **Locked MOVE buys real progress.** Everything that makes the game deeper — capturing, upgrading, fortifying, running a club, entering events — is purchasable with it. A free player is never blocked from the fun.
- **Landowners pay first.** Nobody earns Liquid rewards without having already spent to acquire land and continuing to spend to defend it. They are net contributors to the economy before they are beneficiaries of it.
- **Free players create the value.** Density is what makes land worth owning and what makes sponsorship worth buying. Free players are not a cost centre — they are the reason the economy exists at all.

TIER	ENTRY	EARNs	SELLABLE	ROLE IN THE ECONOMY
Free Explorer	Free	XP + Locked	No	Creates activity and density
Verified Explorer	Free + verification	Higher XP + Locked	No	Trusted route contributor
Deed Holder	Claim or buy land	Locked + Liquid	Yes	Land economy and liquidity
Club Operator	Club deed or pass	Club rewards + fees	Limited	Organises the community
Sponsor Partner	Campaign fee	Foot traffic + exposure	—	Brings real money in

Design principle: nobody needs crypto to enjoy the map, but the deepest economic layer belongs to people who own and maintain land.

What two states do to sell pressure

A worked example with round numbers. It shows how a thousand rewarded players can produce only a fraction of a thousand players' worth of selling.

ASSUMPTIONS IN THIS EXAMPLE

ILLUSTRATIVE

- 1,000 active players in a city, split 60% free / 40% landowners
- Free players average 100 Locked MOVE over the period; landowners average 75 Locked + 100 Liquid
- Roughly 30% of Liquid rewards are spent back into the game rather than sold
- These are round illustrative figures chosen to show the shape of the maths, not measured behaviour

PLAYER TYPE	PLAYERS	LOCKED MOVE	LIQUID MOVE	TOTAL EARNED
Free players	600	60,000	0	60,000
Landowners	400	30,000	40,000	70,000
Total	1,000	90,000	40,000	130,000

Of 130,000 tokens rewarded, how much can ever reach a market?

After some Liquid is spent back into the game, roughly 22% of all rewards can reach a market.

A thousand rewarded players; roughly two hundred players' worth of possible selling. That gap is the mechanism.

Reading the result

69%

of all rewards are structurally unable to be sold — ever

31%

is the theoretical maximum that could reach a market

~22%

is the realistic exposure after in-game spending

The project gets a thousand engaged players, and the market absorbs roughly a fifth of what a naive design would have dumped on it. Free players still feel genuinely rewarded — their balance buys real progress. Landowners still get real, sellable upside. Nobody is being tricked, and the token is not being buried under its own rewards.

THE COMPARISON WORTH DRAWING

In a single-state economy, all 130,000 tokens would be immediately sellable and most would be sold. The two-state design does not reduce how rewarded people feel — it reduces how much of that reward has to be absorbed by buyers. That is the difference between an economy that compounds and one that dilutes.

Where new tokens come from

Not a fixed rate per kilometre for ever. Rewards come from a **capped seasonal pool** that every active player shares — and the pool shrinks every season on purpose.

The formula, in words

Your reward = the season pool × (your activity score ÷ everyone's activity score)

More players means more competition for the same pool. Fewer players means the active ones earn more.

This one change fixes the deepest flaw in the old move-to-earn model. Under a fixed rate per kilometre, ten times as many users automatically means ten times as many tokens printed — growth itself destroys the economy. Under a pool, **growth cannot inflate supply**. It only changes how the same fixed amount is divided.

The emission schedule

PLANNED — THE DEPLOYED CONTRACT DOES NOT YET DO THIS

Tokens
issued

Four 90-day seasons make one year. Total year-one issuance: **26.6 million \$MOVE** — just 2.7% of the maximum supply.

Why a shrinking pool is the right shape

- **Early players are rewarded more, and should be.** They take the most risk and do the hardest work — populating an empty map.
- **Supply cannot run away.** Even unlimited user growth cannot print an extra token.
- **It forces the economy to mature.** As emissions fall, the value of holding land, earning land tax, and real sponsor money has to take over. That transition is the whole business plan, and the schedule makes it non-optional.

TWO HONEST GAPS YOU SHOULD KNOW ABOUT BEFORE ANYONE ELSE FINDS THEM

1. The deployed contract does not do this yet. Our live test contract mints a fixed 10 \$MOVE per kilometre with a halving every six months — the older design. Moving to seasonal pools requires a new contract version. It is on the plan and it is not yet built.

2. The schedule and the distribution do not currently reconcile. Shrinking 20% per season converges to about **45 million \$MOVE issued in total, ever** — but our stated distribution reserves **600 million** (60%) for player rewards. Those two numbers are 13× apart. Either the decay must flatten to a sustaining level after the first years, or the reward allocation is far larger than the emission plan needs. **This must be resolved before any public tokenomics is published.** Section 30 lists it as an open item.

HOW TO PRESENT THIS

Finding your own inconsistency and naming it is a strength, not a weakness. The wrong move is to publish two numbers that a diligent analyst can pull apart in ten minutes. The right move is: *"here is our emission curve, here is our allocation, we know they do not yet reconcile, and here are the two ways we can close it."*

The four safety valves

A capped pool sets the ceiling. Four automatic valves sit underneath it, each able to reduce rewards further when the economy is not healthy. None of them can increase rewards.

1

Burn valve
If players are not spending enough of what they earn, the next pool is cut automatically.
Live in our contract: burn/mint under 0.7 → -10% rate

2

Revenue valve
Sellable rewards cannot grow faster than the real money the business is actually earning.
Ties the token directly to business performance

3

Locked buffer
Free-player rewards never leave the app, so most growth adds engagement, not sell pressure.
Roughly 69% of rewards in our worked example

4

Deed eligibility
Only players who own land and stay active can earn sellable rewards at all.
You must spend into the economy before you earn from it

Four independent brakes. Any one of them tightening reduces issuance; none of them can loosen it.

The one that investors care about most

Valve 2 — the revenue valve — is the differentiator worth leading with. It says: **the amount of sellable reward the protocol issues is bounded by the real revenue the business generates**. If sponsorship and subscription income grow, the reward pool can be supported. If they do not, rewards tighten automatically rather than being propped up by new buyers.

That single rule turns the token from a promise into a claim on demonstrated business performance, and it means the honest answer to "what backs \$MOVE?" is "a real revenue line, and a cap that respects it" rather than "belief".

Plus the caps already live in the contract

FROM OUR CODE

CONTROL	EFFECT
Hard supply cap	1,000,000,000 \$MOVE — the contract cannot exceed it
Daily cap per address	200 \$MOVE at launch, halving each epoch
Distance ceiling per route	100 km — no single submission can claim more
One-use route proofs	The same route can never be claimed twice
Gear boost ceiling	3× maximum, whatever the combination
Emission floor	The auto-valve cannot drive rewards below 0.01 \$MOVE/km

Where tokens go to die

Sinks are the half of tokenomics that the failed generation skipped entirely. Ours are designed so that spending feels like *strategy* — ownership, defence, status, competition — rather than like paying a toll.

Eight ways \$MOVE leaves circulation

Claiming land scales with demand	Fortifying 300 each, max 3	Challenging a rival 100 to declare	Buying time 500 to extend
Gear boosts, per item	Club upgrades tools, banners, events	Cosmetics skins, badges, frames	Landmark auctions rare city zones

The design goal

Free players spend Locked MOVE to play deeper. Landowners spend to protect their upside. Sponsors refill prize pools with real money.

Every one of these is something a player wants to do. That is what separates a sink from a tax.

The costs already written into our contracts FROM OUR CODE

ACTION	COST	WHO PAYS IT
Claiming a Zone Deed	$500 \times \sqrt{\text{(weekly movers)}}$	The claimer
Declaring a challenge on someone's land	100 \$MOVE	The challenger
Stronghold boost while defending	300 \$MOVE $\times$ up to 3	The defender
Extending a challenge window	500 \$MOVE	The defender
Minting gear	varies by item	The buyer
Season-end Great Burn	10% of top-100 land yield	Top landowners

A worked example of how much a contested cell consumes

Imagine a busy high-street cell with 25 distinct movers per week, contested once during a season:

EVENT	\$MOVE DESTROYED
Owner claims the cell — $500 \times \sqrt{25}$	2,500
A rival declares a challenge	100
Owner fortifies twice to hold it	600
Owner extends the window once	500
Total consumed by one contested cell, one season	3,700

For scale: at the current contract rate, that is the entire reward from **370 kilometres** of verified movement, destroyed by a single well-fought cell.

ONE SINK DOES NOT CURRENTLY WORK

Our deployed contract's "Great Burn" moves tokens to the treasury rather than destroying them — so supply is unchanged. It is catalogued in our own contract-defect register and must be fixed in the next contract version, or renamed honestly. **Do not describe the Great Burn as deflationary until that is done.**

Land as a business unit

A Zone Deed is not a collectible sitting in a wallet. It is playable, defensible, tradable, rentable, and sponsorable — and each of those verbs is a revenue line.

LAYER 1	Common tiles Free players capture and hold quiet areas with XP and Locked MOVE. No cost, no trading.
LAYER 2	Zone badges Non-transferable proof of local dominance, streaks, reconquests, city participation. Status, not asset.
LAYER 3	Zone Deeds Tradable land for premium cells. Earns land tax, eligible for Liquid rewards, can be sold, leased, or sponsored.
LAYER 4	Sponsored zones Brands and Base projects fund challenges around real locations, routes, and city campaigns. This is where outside money enters the economy.

Four layers of land. Value and revenue both increase as you go down.

Six ways a single cell generates value

MECHANISM	HOW IT WORKS	WHAT IT PRODUCES
Claim fee	Claimer burns \$MOVE scaled to demand; platform takes a fee	Company revenue + token burn
Land tax	2% of everything minted in the cell goes to its holder FROM OUR CODE	Owner income; a reason to hold
Secondary trading	A fee on land changing hands 2.5–5%, ILLUSTRATIVE	Recurring transaction revenue
Maintenance	Owners spend to fortify and defend	Burn pressure + engagement
Club leasing	Owners lease control rights to clubs or events	Owner utility + platform fee
Brand wrap	The cell becomes a sponsored challenge location	External revenue, no dilution

THE STRATEGIC POINT

Notice that four of these six produce income for the *company* and two produce income for the *player* — and none of them requires the token to appreciate. **A deed is a small business, and the platform takes a cut of its activity.** That is a far more durable structure than "we hope the NFT goes up".

Only real movement earns

Every token and every deed depends on one thing being true: the movement actually happened. If someone can fake a walk from their sofa, the entire economy is worthless. This is the hardest technical problem we have.

Route plausibility LIVE

Speed, distance, timing, and continuity are checked. Anything implying more than ~80 km/h is rejected — which catches the simplest cheat, which is driving.

Signal quality LIVE

Phones report how confident they are in each position. A session where too many points are vague is rejected, because vague points are how spoofing tools hide.

One-use proofs LIVE

Each route is compressed into a unique fingerprint that can be claimed exactly once. You cannot record one good walk and submit it a hundred times.

Economic caps LIVE

Even a perfect cheat is bounded by a hard daily limit per address, and a cell needs **5 distinct movers over 90 days** before it is worth anything.

Device integrity PLANNED

Real-device attestation and emulator resistance, so a farm of virtual phones cannot pose as a neighbourhood.

Social corroboration PLANNED

Cross-checking against nearby activity and route patterns. A cell where only one account ever appears is treated with suspicion.

Trust score PLANNED

Risk-based reward limits and a manual review queue, so unusual accounts earn less until they establish a history.

Stake-to-earn slashing PLANNED

Landowners have deposits at stake. Proven cheating costs them their deposit and their eligibility — cheating becomes expensive rather than free.

SAY THIS HONESTLY, BECAUSE IT IS THE STRONGEST ANSWER

No GPS system on earth is perfectly spoof-proof, and we do not claim to be. What we claim is **layered defence**: several independent checks a cheater must defeat simultaneously, plus economic caps that make the effort not worth the reward. Verification is treated as a permanent ongoing investment, not a solved problem. An investor who has seen other projects claim "unspoofable" will trust this answer far more than a confident one.

The legal posture that follows from all this

Free rewards are **non-transferable in-app credits** — closer to loyalty points than to money. Sellable rewards are **capped, activity-based, and gated by eligibility**, with clear user disclosures and region rules. Nothing in the product is offered as income, investment, or return. This posture is not decoration: it is what keeps a movement game a game rather than a financial product, in every market we might launch in.

The complete picture

Everything in Parts A and B on one page. Blue arrows are tokens moving; gold arrows are real money moving. Notice they meet in only two places.

The two economies touch in exactly two places: sponsors pay to reach players on the land layer, and revenue sets the ceiling on sellable rewards. Everywhere else, tokens and cash stay separate.

THE FIVE SENTENCES THAT SUMMARISE THE WHOLE DESIGN

1. Tokens are only created for proven movement, from a pool that shrinks every season.
2. Most rewards are locked and can never be sold, so growth adds engagement rather than sell pressure.
3. Sellable rewards go only to people who have already spent on land and keep defending it.
4. Playing the game destroys tokens faster than most players earn them.
5. The company's income comes from sponsors and subscribers paying real money, not from the token.

How the business actually earns

Eight revenue streams, which group into four engines. Not one of them requires the token to be worth anything, and not one of them charges an ordinary player to play.

ENGINE 1 — STRONGEST

Sponsors & brands

- Local zone sponsorship
- City war campaign packages
- Foot-traffic analytics dashboards

ENGINE 2

Land economy

- Deed claim fees
- Marketplace fee on land trades
- Landmark auctions and leasing

ENGINE 3 — MOST PREDICTABLE

Subscriptions

- MovenRun Premium, monthly
- Club tools for organisers

Recurring, forecastable, chain-independent

ENGINE 4

Events

- Marathon and race collectibles
- City events and charity runs

Lumpy but high-value; strong partnerships

Four engines with genuinely different risk profiles. If any one underperforms, the others are unaffected.

Why this mix is deliberately diversified

ENGINE	PREDICTABILITY	DEPENDS ON TOKEN?	DEPENDS ON WHAT
Sponsors	Medium — contract-based	No	Local player density
Land economy	Low — activity-driven	Partly	An active land market
Subscriptions	High — recurring	No	Product quality and habit
Events	Low — lumpy	No	Partnerships and calendar

THE LINE TO USE WITH INVESTORS

Three of our four revenue engines work identically whether \$MOVE is worth ten dollars or nothing. That is the structural answer to the obvious question — "what happens to your business in a crypto bear market?" — and very few projects in this category can give it.

What we deliberately do not charge for

- **Playing.** Moving, capturing, streaks, clubs, and city competition are free for ever. Charging here would kill the density that everything else depends on.
- **Basic access.** No paywall, no trial, no "premium required to earn". Premium buys convenience and insight, never earning power.
- **Getting started with crypto.** Wallets are free, fees are sponsored, nothing must be bought to claim a first zone.

Sponsors: the strongest line

Our best revenue does not come from users buying tokens. It comes from businesses paying to reach people who are physically walking past their door.

What a sponsor is actually buying

A café that sponsors the cell it sits in is not buying an advert. It is buying a reason for players to **choose a route that goes past it** — and then a report showing how many people did. That is closer to a shop paying for a map pin than to a banner ad, except that players actively *want* to visit because it advances their game.

Verified footfall
Not impressions, not clicks — people who genuinely, physically moved through a location, proven by the same verification that guards our token.

A measurable campaign
A sponsor can see how many players entered the zone, how often they returned, and how it compares to before the campaign.

Goodwill, not intrusion
Sponsored zones give players extra rewards and objectives. The sponsor is funding the fun, not interrupting it.

Indicative packages

ILLUSTRATIVE — NO SIGNED CUSTOMER HAS VALIDATED ANY OF THIS

PACKAGE	PRICE	TYPICAL BUYER
Local zone sponsor	\$300 – \$1,000 / mo	Running stores, gyms, cafés, campus clubs
City war sponsor	\$10K – \$50K / season	Base projects, fitness brands, consumer apps
Marathon / event drop	\$5K – \$100K / event	Race organisers, city events, charity runs
Analytics dashboard	\$1K – \$5K / mo	Multi-location brands running campaigns

Outside money buys activity; activity makes land and footfall more valuable; that makes the next sponsor easier to sign.

THE HONEST STATE OF THIS LINE

We have **no signed sponsors and no validated pricing**. The packages above are our model, informed by what comparable local-marketing spend looks like, not by a single closed deal. The first paid sponsor is one of the most important milestones in the plan precisely because it converts this page from a theory into evidence.

Premium, without a paywall

Subscriptions are the most predictable revenue a consumer app can have. The rule we set ourselves: premium may improve *convenience*, *insight* and *status* — never earning power.

MovenRun Premium — \$9.99 / month ILLUSTRATIVE

Not a paywall. Earning stays controlled by land ownership and season pools, for subscribers and non-subscribers alike.

Advanced map tools

Heatmaps, personal territory analytics, rival tracking, and route planning — for players who want to play strategically rather than casually.

Gasless convenience

Sponsored claims and simplified wallet handling for frequent actions. Saves steps, not money the user would otherwise pay.

Club perks

Priority club creation, private boards, member roles, and event tools. Aimed squarely at the organisers who bring thirty players each.

Privacy controls

Private route mode, masked home zone, and advanced safety settings. A genuinely valuable feature for anyone uneasy about location.

Premium cosmetics

Exclusive map skins, badges, profile frames, and share cards. Status is a real motivator in a competitive territory game.

Event access

Early access to sponsor runs, city wars, and limited challenge drops.

PRICING SENSITIVITY — THE ASSUMPTION MOST WORTH TESTING

\$9.99/month puts us at the same price as established fitness subscriptions from companies with years of trust and far more features. For a new app that is ambitious. Two things follow: **expect a lower conversion rate than a mature product**, and **consider testing a lower tier** (a \$3–5 "club organiser" or "privacy" tier) before assuming the headline price. Section 22 shows what happens to our model if conversion is a third of the optimistic case.

Why the "never earning power" rule is non-negotiable

The moment a subscription increases what a player earns, three bad things happen at once. The game becomes pay-to-win, which drives away the free players whose density everything depends on. The rewards become harder to describe as a game feature and easier to describe as a financial return, which is a regulatory problem. And the sponsor proposition weakens, because footfall starts reflecting who paid rather than who genuinely moves. Holding this line costs us some short-term revenue and protects the entire model.

What it costs to run

Revenue slides are easy. The question an investor asks next is what it costs to serve a player — and here the answer is unusually good, because our expensive resource is people, not infrastructure.

The cost of putting a player on the blockchain

We sponsor every user's transaction fees, so their cost lands on us. This is the number people assume will be crippling, and on Base it simply is not:

ASSUMPTION	ILLUSTRATIVE	VALUE
On-chain actions per active player per month		20
Typical cost of one action on Base		\$0.005
Gas cost per player per month		\$0.10
Gas cost per player per year		\$1.20
At 100,000 monthly active players		≈ \$10,000 / month

On Ethereum's base layer the same 20 actions could cost several dollars each — the same product would be economically impossible. This single line is why the choice of Base is a business decision, not a technical preference.

The rest of the cost base

COST	BEHAVIOUR	NOTES
Team	Fixed, dominant	Engineering, design, city operations. This is 80%+ of spend at every stage and the only cost that really matters early.
Sponsored gas	Scales per player	~\$1.20 per player per year. Negligible.
Infrastructure	Steps up in blocks	Servers, database, queues, map and location services. Hundreds of dollars monthly at city scale.
Wallet provider	Per active user	Typically priced per monthly active wallet. Currently unknown — we have not selected a vendor, so this is a genuine open cost.
City operations	Per city launched	Local partnerships, club outreach, events. The real cost of the growth model, and mostly people-time.
Compliance & audit	Lumpy, significant	An external smart-contract audit before mainnet is a hard requirement and a meaningful one-off cost.

THE STRUCTURAL ADVANTAGE

Serving one more player costs us close to nothing — roughly a dollar a year in fees plus a fraction of shared infrastructure. Almost all our cost is fixed team cost. **That means gross margins are very high and the entire question is whether we can reach enough players to cover a fixed team cost** — which is exactly the shape of a software business, and exactly what a software investor knows how to underwrite.

THE HONEST GAP

We have not selected an embedded-wallet provider, and their pricing is typically per monthly active wallet. At large scale that could become one of our few genuinely per-user costs. Until a vendor is chosen, treat wallet cost as an **unknown** in any model — including ours.

One city, one thousand players

The important property of this model is that it earns *before* scale. Land and sponsors are local, so a single well-populated city can produce revenue long before a global user base exists.

EVERY ASSUMPTION IN THIS MODEL

ILLUSTRATIVE

- 1,000 monthly active players in one city, roughly 60% free / 40% landowners
- 120 land claims per month at an \$8 platform fee
- \$15,000 of monthly land trading at a 2.5% fee
- 5 local sponsors at \$300/month — the entry-level package
- 5% subscription conversion (50 players) at \$9.99
- 20 club organisers on tools at \$9, and 300 event claims at \$2
- None of this is validated by a paying customer. It is arithmetic, not evidence.

REVENUE STREAM	ASSUMPTION	MONTHLY
Local sponsors	5 × \$300	\$1,500
Zone Deed claim fees	120 × \$8	\$960
Event drops	300 × \$2	\$600
Premium subscriptions	50 × \$9.99	\$500
Marketplace fees	\$15K volume × 2.5%	\$375
Club tools	20 × \$9	\$180
Total revenue	One starter city	\$4,115 / mo
Sponsored gas	1,000 × \$0.10	– \$100
Infrastructure	Baseline servers, database, queues	– \$400
Wallet provider	Estimated per active wallet	– \$50
Contribution after direct costs	≈ 87% margin	\$3,565 / mo

Contribution margin, not profit. Team salaries are excluded — at this stage they are the whole cost base, and one city does not cover them. The point of this table is the *shape*: revenue per city arrives early, and serving those players costs almost nothing.

Where the \$4,115 comes from

Revenue vs the cost of serving those players

Sponsors are the largest line even at the smallest scale — which is why the first signed sponsor matters more than the first thousand users.

WHAT THIS MODEL IS REALLY CLAIMING

Not that we will earn \$4,115 a month. It is claiming something more useful: **the revenue model does not require millions of users to switch on.** One dense city with a handful of local sponsors already produces a real, if small, income — which means the business can be tested for a few thousand dollars of revenue rather than a few million.

At scale — and the honest downside

Most decks show only the optimistic column. Showing both is more persuasive, because the first thing a serious investor does is rebuild your model with their own assumptions.

STREAM	OPTIMISTIC CASE	MONTHLY	CONSERVATIVE
Marketplace fees	\$10M volume × 2.5%	\$250,000	\$25,000
City war sponsors	10 campaigns × \$25K	\$250,000	\$45,000
Zone Deed claims	20,000 × \$10	\$200,000	\$50,000
Brand zones	100 × \$1,500	\$150,000	\$40,000
Event drops	50,000 × \$3	\$150,000	\$45,000
Sponsor dashboards	50 × \$2,000	\$100,000	\$30,000
Premium subscriptions	8% of users × \$9.99	\$79,920	\$29,970
Club tools	2,000 × \$19	\$38,000	\$11,400
Total at 100,000 players	per month	\$1.22M	\$276K
Annualised		\$14.6M	\$3.3M
Revenue per player / month	ARPU	\$12.18	\$2.76
Direct cost to serve	gas + infra + wallets	− \$23,000	− \$23,000
Contribution margin		98%	92%

THE CONSERVATIVE COLUMN ASSUMES ILLUSTRATIVE

- Subscription conversion of **3%**, not 8% — closer to typical consumer freemium
- Land trading volume **ten times lower** at \$1M/month
- A quarter as many land claims, and roughly a third of the sponsor and event activity

THE ASSUMPTION MOST LIKELY TO BE ATTACKED

\$10M of monthly land trading at 100,000 players is \$100 per player per month of trading volume. That is a very active market — plausible for a mature, sought-after land economy, aggressive for a young one. Expect an investor to strike it out entirely. Notice that even at a tenth of it, the business still annualises above \$3M with a 92% contribution margin. **Lead with the conservative column and let them find the upside themselves.**

A team of around twenty people at that scale might cost \$200–300K a month. So the optimistic case is comfortably profitable, and the conservative case is roughly break-even on a fully-loaded basis — which is a perfectly respectable place for a consumer network to be at 100,000 users, with four independent levers still to pull.

The economics of one player

Investors reduce every consumer business to three numbers: what a user is worth, what they cost to acquire, and how long it takes to get that money back. Here they are, with the caveat that none is yet measured.

\$2.76

Revenue per player per month, conservative case ILLUSTRATIVE

~\$1.20

Direct cost to serve one player for a whole year

>90%

Contribution margin in both cases

Why our acquisition cost should be unusually low

Most consumer apps buy users through advertising, at anywhere from a few dollars to tens of dollars each. Three properties of this product cut that cost structurally:

- **Clubs arrive pre-formed.** Running clubs, walking groups, and gyms already exist and already meet. One captain converts thirty players in a single conversation — thirty players in one neighbourhood, which is also exactly the density we need.
- **Territory is inherently shareable.** A map of your neighbourhood in your colour provokes *"that's my street — why is it yours?"*. A distance number does not.
- **Rivalry recruits.** A player losing ground to a neighbour has a direct incentive to bring friends. The game mechanic is the referral mechanic.

METRIC ILLUSTRATIVE	CONSERVATIVE	OPTIMISTIC
Revenue per player / month	\$2.76	\$12.18
Cost to acquire a player (blended)	\$5.00	\$2.00
Months to pay that back	1.8	0.2
Assumed average player lifetime	12 months	18 months
Lifetime value per player	≈ \$33	≈ \$219
Value-to-cost ratio	6.6×	100×+

Investors generally look for a ratio above 3× and payback inside 12 months. Both cases clear that comfortably — but every input above is modelled, not measured. The number that matters is the first one we actually observe.

WHAT WOULD BREAK THIS

Retention. Every figure above assumes players stay for a year. A movement app lives or dies on habit formation, and if week-4 retention is poor, lifetime value collapses regardless of how good the margins look. **Retention is the number we should be most impatient to measure, and the one an investor will ask for first.**

What investors actually score

At our stage nobody is valuing revenue, because there is none. They are scoring six things — and knowing which ones we are strong on tells you what to lead with.

WHAT THEY SCORE	THE QUESTION BEHIND IT	WEIGHT AT PRE-REVENUE
Team	Can these people build and ship the hard part?	Highest
Evidence of work	Is there something real, or just a deck?	Very high
Market	If it works, is the prize big enough to matter?	High
Moat	What stops a funded competitor copying it in a quarter?	High
Economic design	Does this survive contact with real incentives?	Medium-high in crypto
Timing	Why is now the moment, rather than two years ago?	Medium

The three things that specifically raise a crypto project's score

Revenue that is not the token

The single strongest signal after the 2022 collapse. It says the business survives a bear market.

Sinks designed before incentives

Shows the team understood why the previous generation failed rather than repeating its pitch.

Verifiable, shipped work

Deployed contracts and passing tests anyone can check beat any amount of narrative.

And the three that lower it fastest

Projections presented as facts

One unlabelled model figure and everything else you said gets re-examined.

Hidden problems

Anything they discover that you did not volunteer costs far more than the problem itself.

Token-price-dependent plans

"It works if the token appreciates" is read as "it does not work".

THE POSTURE THAT WINS

Lead with what is **built and checkable**, label every model as a model, and volunteer your own open problems before they are found. Counter-intuitively, a founder who says *"here are three things wrong with our contracts and here is the fix plan"* scores higher than one who claims everything is finished — because the first is describing a process the investor can trust, and the second is describing a claim they now have to verify.

Our honest scorecard

Where MovenRun is genuinely strong, and where it is not. No self-awarded score — just the two columns, so you can hold both in a conversation.

An honest read. The two weakest bars are the two things funding is meant to fix.

What is genuinely strong

- **The hard part was built first.** Eight smart contracts written, tested, and deployed to Base's public test network — 49 passing tests — before asking anyone for money.
- **Verifiable, not narrative.** Every contract address is public and checkable by a stranger in five minutes.
- **Unusual defect honesty.** We wrote tests that prove our own deployed contracts are flawed, published the severity register, and named two of our own issues critical.
- **Security engineering above stage.** A documented threat model, a 52-point control checklist, thirteen architecture decision records, and a key-rotation runbook.
- **Revenue independent of the token.** Three of four engines are unaffected by token price.
- **Sinks before incentives.** The economy is designed so playing consumes more than most players earn.

What is genuinely weak

- **No users, no revenue, no signed sponsor.** Everything commercial in this document is a model.
- **The layers are not yet connected.** The app, the verification service, and the contracts each work; none has ever run end to end together.
- **No wallet provider selected,** so "invisible onboarding" — the entire strategic bet — cannot yet be demonstrated to anyone.
- **Deployed contracts need a V2.** Fifteen catalogued logic defects, two critical. Not patchable; requires redeploy and migration.
- **No external audit yet** — a hard prerequisite before real value moves.
- **Retention is unmeasured.** The number the whole model rests on is the one we do not have.

The Base ecosystem thesis

Our first community should not be "global fitness". It should be Base itself — projects, cities, clubs, creators and sponsors already competing for attention, given a physical arena to compete in.

Base City Wars

Cities compete for seasonal territory. Base projects sponsor teams and prize pools — a ready-made sponsor pipeline that already has budget and already wants reach.

Project clubs

Every protocol on Base can form a running club and compete publicly. Teams that already have communities bring them with them.

Builder miles

Founders, developers, creators, and communities earn movement badges. A social object that circulates inside exactly the network we want to reach.

Protocol zones

Partner projects sponsor branded zones with on-chain proof of participation — sponsorship that is native to the ecosystem rather than borrowed from web2.

Gasless claims

Free players claim badges and zones without ever holding a gas token. Removes the step where most newcomers give up.

Share-card virality

Base-native share cards, leaderboard claims, and invites turn every captured district into distribution.

WHY THIS IS THE RIGHT FIRST MARKET

Base is explicitly looking for consumer applications that bring non-crypto users on-chain — that is what its accelerator exists to fund. We are a consumer product whose entire design goal is exactly that, and whose contracts are *already deployed on Base's own test network*. **The fit is structural, not opportunistic.** And unlike a general fitness launch, the Base community is reachable, concentrated, competitive, and already holds budget for sponsorship.

What being a flagship Base consumer app is worth

- **Distribution most consumer apps cannot buy.** Ecosystem promotion to an audience actively looking for apps to try.
- **A warm sponsor pipeline.** Base projects sponsoring city wars are a far shorter sales cycle than cold-calling cafés — and they prove the format before we take it to local business.
- **Credibility with partners.** Base is operated by a large regulated company, which matters when a council or a race organiser is deciding whether to work with us.
- **Density by default.** A concentrated community launching together solves the cold-start problem that geography would otherwise make brutal.

What funding actually buys

A specific plan for a \$100K programme grant. The test of a good use-of-funds page is whether every line converts an unknown into a measured fact.

ALLOCATION	WHAT IT PAYS FOR	WHAT IT CONVERTS
Engineering \$40K	Connect the app, verification service, and contracts end to end; real hexagon capture; integrate a wallet provider so onboarding is genuinely invisible	Turns "we built the hard parts" into a working demonstration
Audit & V2 contracts \$25K	New contract version fixing the fifteen catalogued defects, plus an external security audit	Turns a testnet reference into something that can hold real value
First city operations \$20K	Club partnerships, launch events, local sponsor sales, community management in one chosen city	Turns an assumed model into measured retention and a first paid sponsor
Infrastructure \$8K	Hosting, database, queues, wallet provider fees, sponsored gas for twelve months	Keeps the service running through the whole proving period
Legal & compliance \$7K	Review of the reward structure, disclosures, and regional posture	Turns "we think this is a game not a security" into advice we can rely on

The four milestones this should produce

1 • One complete vertical slice

A real walk in the app, verified, producing a real on-chain capture visible back in the app. The whole product thesis, demonstrated once.

2 • One city with measured density

1,000+ monthly active players in a single city, with real week-4 retention and contested-zone numbers.

3 • First three paid sponsors

Signed, invoiced, and reported on — converting the strongest revenue line from theory to evidence.

4 • Audited V2 contracts

Fixed, externally reviewed, and ready for the mainnet decision.

THE FRAMING THAT WORKS

Do not ask for money to "build the product" — the product substantially exists. Ask for money to **convert four specific unknowns into four measured facts**. Investors fund de-risking far more readily than they fund construction.

The questions you will be asked

Ten questions, with answers that are accurate and correctly hedged. Learn the shape of these rather than the words.

1 · How is this not another move-to-earn that collapses?

Three structural differences. The asset is **territory**, not a token balance, so progress is ownable rather than only sellable. **Sinks were designed before incentives** — you must spend to claim, fortify, and defend, so demand does not depend on new buyers. And **most rewards can never be sold at all**: free players earn a locked, non-transferable credit. On top of that we have an enforced internal rule blocking any tradeable economy until verification, density, and real sponsor demand are all proven.

2 · What happens to your business if the token goes to zero?

Three of our four revenue engines are unaffected — sponsorship, subscriptions, and events are paid in ordinary money by people who want footfall, tools, or a race experience. The land economy would be hurt. The company would not be existentially threatened, which is precisely the structure the last generation lacked.

3 · What stops people faking GPS?

Layered defence: a speed gate, an accuracy gate, continuity and duration checks, a route fingerprint usable exactly once, a cryptographic signature the contracts require, a hard daily cap per address, and a rule that a cell needs five *distinct* movers over ninety days before it is worth anything. No GPS system is perfectly spoof-proof and we do not claim to be — we claim several independent checks a cheater must beat at once, plus caps that make it not worth the effort.

4 · Why will anyone sponsor a zone?

Because they are buying verified physical footfall with a measurable report, not impressions. A café gets players choosing routes past its door and a dashboard showing how many did. Honest caveat: **we have not signed one yet**, and doing so is one of our top milestones.

5 · What is your actual traction?

Zero users and zero revenue. What we have is verifiable engineering: eight contracts deployed to Base's test network with 49 passing tests, a working GPS verification service, a security and identity foundation, and a mobile app with real movement tracking. We are pre-traction and precise about it.

6 · What is the biggest risk?

Density, not technology. A territory game with no neighbours is a lonely map, and reaching enough players in one city is harder than anything in our codebase. Our whole go-to-market — clubs, city-by-city launch, Base-native competition — exists to attack that one risk.

7 · What stops a bigger company copying this?

The app can be copied in a quarter. What cannot is the fact that the people in a neighbourhood already hold the ground around their streets, the sponsor relationships in that city, and a verification system that is genuinely hard to get right. The moat is geographic and social, and it only exists where we have already won.

8 · Is the token a security?

Our design is deliberately built to avoid that: free rewards are non-transferable in-app credits closer to loyalty points; sellable rewards are capped, activity-gated, and never offered as income or return; nothing is sold to the public today. We have not yet taken formal legal advice, and doing so is a funded line in our use of funds. **Never assert a legal conclusion we have not paid someone to give us.**

9 · Your contracts are already deployed — are they safe?

The deployed version is a **testnet reference implementation, not production-ready**. We catalogued sixteen defects ourselves, two of them critical, each proven by a passing test, and published the register. They require a V2 redeploy plus an external audit before real value moves. Volunteering this is the strongest available answer, because the alternative is them finding it.

10 · Why now, and why you?

Now, because embedded wallets and sponsored fees have only recently matured enough to hide crypto completely — two years ago every user would have had to buy a token before their first walk — and because fees on Base are finally low enough for a game with thousands of small daily transactions. Us, because we built the difficult half first and can point at it, and because we have shown we would rather publish our own defects than ship on top of them.

The numbers that will prove it

Everything in Part C is a model until these are measured. This is the list we should be impatient about, in the order the evidence should arrive.

METRIC	WHY IT MATTERS	HEALTHY	WHAT IT PROVES
Week-4 retention	Habit formation	> 25%	Everything. Lifetime value collapses without it.
Active players per city	Density, not downloads	1,000+	That the territory game actually works socially
Contested zone ratio	Rivalry is live	> 20%	That the map is a contest, not a colouring book
Install → first session	Onboarding friction	> 40%	That invisible crypto onboarding genuinely works
Sessions per active week	Consistency beats intensity	3+	That it became a habit rather than a novelty
Club participation	Social retention	> 30%	That our cheapest acquisition channel is real
Signed sponsors	Revenue validation	3 in city one	That the strongest revenue line exists
Sponsor renewal rate	Real value delivered	> 60%	That sponsorship is a business, not a favour
Subscription conversion	Willingness to pay	3–5%	Whether \$9.99 is the right price
Verified vs rejected routes	Anti-cheat health	stable	That the economy's foundation is sound

THE TWO THAT MATTER MOST

Week-4 retention and the first renewed sponsor. The first tells you whether people form a habit, which drives every number in Part C. The second tells you whether anyone will pay for the audience that habit creates. Every other metric is a detail next to those two.

The sequence the evidence should arrive in

Each step is a precondition for the next. Skipping one is how this category fails.

Open items and disclosures

Everything in this document that is unresolved, in one place, so nobody is surprised by it later — including you.

Economic questions we have not yet answered

OPEN ITEM	WHY IT MATTERS AND WHAT HAS TO HAPPEN
Emission schedule vs allocation	Shrinking pools 20% per season total roughly 45M \$MOVE ever, but the stated distribution reserves 600M for players. These must be reconciled before any tokenomics is published. Either the decay flattens after the early years, or the allocation is far larger than needed.
Contracts do not match the design	The deployed contract mints per kilometre with halvings; the design calls for seasonal pools. Requires a V2 contract.
The Great Burn does not burn	It currently transfers to the treasury, leaving supply unchanged. Fix it or rename it — do not call it deflationary meanwhile.
Wallet provider cost unknown	No vendor selected, and pricing is usually per active wallet. One of few genuinely per-user costs, currently unmodelled.
Subscription price untested	\$9.99 matches mature fitness apps. A lower entry tier may convert far better.
Land trading volume unproven	The most aggressive assumption in the scale model, and the first line an investor will delete.
No legal opinion yet	Our reward structure is designed to be a game feature, not a financial product — but that is our design intent, not counsel's conclusion.

Standing disclosures

- MovenRun is a development-stage product. Features, parameters, and timelines described here may change. Nothing in this document is financial advice, an offer, a solicitation, or a promise of returns.
- \$MOVE does not trade. There has been no sale, no listing, no liquidity, and no allocation to anyone. It exists only as a test-network contract with no value.
- Zone Deeds are game assets, not real-world property. They confer no rights over physical land.
- Every revenue figure is illustrative. We have no paying customers and no validated pricing. Models in this document are arithmetic demonstrating structure, not forecasts.

Money words, in one line each

ARPU

Average revenue per user, usually per month.

Burn

Permanently destroying tokens so they can never return to supply.

CAC

Customer acquisition cost — what it costs to get one new user.

Contribution margin

Revenue minus the direct cost of serving it, before team salaries.

Emission

The creation of new tokens as rewards.

Freemium conversion

The share of free users who become paying subscribers. Typically 2–5%.

Gas

The small fee for writing to a blockchain. We pay it for users.

Liquidity

How easily a token can be bought or sold without moving its price.

Liquid MOVE

Reward that can be transferred and sold. Landowners only, capped.

Locked MOVE

Reward that can be spent in-app but never sold. Most rewards are this.

LTV

Lifetime value — total revenue expected from one user before they leave.

Payback period

How long until a user's revenue repays what it cost to acquire them.

Season pool

A fixed quantity of tokens issued over 90 days, shared by activity.

Sell pressure

How much of a token is likely to be sold rather than held or spent.

Sink

Any mechanism that removes tokens from circulation.

Supply cap

The maximum tokens that can ever exist. Ours is one billion.

Unit economics

Whether one customer is profitable, independent of scale.

Zone tax

2% of tokens minted in a cell, paid to that cell's owner.

MovenRun — Economy & Investment Brief, v2.0 · August 2026. Confidential; prepared for internal partner onboarding. Supersedes the Revenue Economy Blueprint v1. Companion to the MovenRun Partner Onboarding Brief v1.0. Figures marked "from our code" are parameters in contracts deployed to Base Sepolia testnet and are independently verifiable; all other figures are illustrative models. Nothing here is financial advice, an offer, or a promise of returns.
